**NetZeroNitrogen wants
bacteria to replace
synthetic fertilizer on
farm fields**

Tim De Chant — 4:00 AM PDT · July 23, 2025

Synthetic fertilizer is a modern wonder, helping to feed billions of people, but it's not without its costs. Fertilizer runoff from farm fields has led to [dead zones](#) in oceans around the world, where low oxygen levels have starved normally teeming coastal waters of life.

Eliminating synthetic fertilizers is a tall order, but one startup thinks that its bacteria can eliminate up to half of it, all while undercutting fertilizer on cost.

[NetZeroNitrogen](#) has developed a suite of bacterial strains that is applied directly to the seed and allows the plant to get nitrogen from the atmosphere instead of chemicals.

IMAGE CREDITS:

DAVID BATTHGATE/CORBIS / GETTY IMAGES

"This is a precision sniper approach," Justin Hughes, co-founder and CEO of NetZeroNitrogen, told TechCrunch. "In contrast to fertilizer, where you spread it all over the field and effectively hope some hits the target, a kind of shotgun approach."

The startup recently raised a \$6.6 million seed round led by World Fund and Azolla Ventures, the company exclusively told TechCrunch.

NetZeroNitrogen's bacteria are the product of over a decade of research on the part of Gary Devine, who has been studying naturally occurring nitrogen-fixing strains. Hughes pointed out that the company's bacteria aren't genetically modified.

The company plans to roll out its first product for rice. It’s partially a marriage of convenience: to apply the bacterial strains, it’s currently easiest to dunk seeds in water containing them. Rice just so happens to be soaked before planting. “You just mix it in at that point and you’re done,” Hughes said.

Because the company can use large fermenters to grow its strains, it can make its bacterial amendment for less than an equivalent amount of synthetic fertilizer, Hughes said. “The costs of production of biomanufacturing are far, far lower than the Haber-Bosch process, especially once you start to scale up,” he said, referring to the process widely used to make fertilizer.

The goal, Hughes added, is to sell NetZeroNitrogen’s bacteria to farmers for at least \$50 per hectare less than they spend on synthetic fertilizers. In regions like Southeast Asia, that could mean a 30% to 40% discount, he said.

For now, synthetic fertilizer won’t be disappearing. “Unfortunately, we can’t quite solve 100% of the problem yet,” Hughes said. “But of the proportion that we can solve, it’s effectively 100% efficiency.”

NovoNutrients wants to turn CO2 into protein

But first it'll have to prove its business model

Tim De Chant

7:00 AM PDT · April 13, 2023

We've spent the last century and a half pumping carbon dioxide into the atmosphere, and it's clear that we'll have to spend the coming decades [removing a significant fraction of that](#).

But then what do we do with it all? Some people are proposing pumping it underground. Others think we can make things from it, including [liquid fuels](#) and [concrete](#). Problem is, those are pretty low-margin opportunities today. One startup thinks the answer is to turn carbon dioxide into protein.

That company is getting a shot to test its thesis at scale, TechCrunch+ has exclusively learned. [NovoNutrients](#) will be building a pilot-scale plant with help from a \$3 million technology and investment deal from Woodside Energy, one of Australia's largest oil and gas companies, which has begun dipping its toes into the carbon capture waters.

NovoNutrients relies on bacteria to do the dirty work. The company has surveyed the scientific literature to find species that can use carbon dioxide in their metabolic pathways, allowing them to use the waste gas as energy. Its scientists have also discovered strains not otherwise known to science.

Advertisement

“Our technology is about how do you industrialize this naturally occurring metabolism?” CEO David Tze told TechCrunch+.

To do that, the company has developed its own bioreactor that helps the bacteria grow in water while consuming carbon dioxide and the other gasses that power its metabolism, including hydrogen and a nitrogen source like ammonia.

The source of the carbon dioxide can be pretty much any operation that’s polluting today, whether that’s oil and gas operations, chemical plants, fertilizer plants or cement plants. All that’s required is a supply of sufficiently concentrated carbon dioxide.

Tech and VC heavyweights join the Disrupt 2025 agenda

Netflix, ElevenLabs, Wayve, Sequoia Capital — just a few of the heavy hitters joining the Disrupt 2025 agenda. They’re here to deliver the insights that fuel startup growth and sharpen your edge. REGISTER NOW

On the other end, NovoNutrients' plants will produce a dry powder that can be refined into a number of different products, including protein supplements for people, animals and farmed fish. Depending on what bacteria are in the tanks, the powder can be tweaked to boost the value of the end product, which might be sold to specialty feed markets for farmers, for example.

NovoNutrients has engineered strains itself to improve their performance, but it also has wild-type and adapted strains. Some of those were obtained by running a fermenter for eight months fed by gasses produced by a cement plant in Cupertino. "We developed strains that grew three times faster than this wild-type strain that we started with," Tze said.

Another way the startup can boost output is by using multiple different strains in one tank. One strain works to break down the primary inputs — carbon dioxide, hydrogen and a nitrogen source — while others go to work on the waste products produced by the first strain. "But more importantly, it means we can tailor the nutrition by adding or subtracting or swapping species or strains with this framework," he added.

At least initially, NovoNutrients won't own any of its commercial-scale plants. Rather, the companies that are producing the pollution will. NovoNutrients will sell the microbes to keep things running, and it'll also take a technology license royalty, Tze said.

"And, of course, we'll provide the whole technology package — both biology and hardware —and work with engineering procurement construction firms, selected by our partner licensee to get that built. We'll train the operating employees and will be available for support."

Advertisement

Partner companies will decide which products they want to produce, though NovoNutrients will help arrange long-term off-take agreements. "If you're an

oil and gas company or some other industrial company, you don't have an established ... business development team that knows how to work with nutrition companies."

Those arrangements position NovoNutrients as a service-oriented company; one that will license its core technology, advise companies on plant construction and operation, and help find buyers for the end product.

Plenty of startups in other industries fell flat when they tried to tackle the whole enchilada. Battery companies circa 2012, for example, definitely bit off more than they could chew and found themselves deep in debt thanks to factories that they were ill-equipped to build, supply and manage. The licensing and service approach may limit the ultimate revenue upside, but it certainly limits the capital risk.

It also lets tech-centered startups do what they do best — focus on the science and technology — while bringing in partners who are well versed in building and operating large capital projects. If NovoNutrients can find enough companies that fit that profile, they might have found a business model that works for them.

Three climate technologies every investor should have in their portfolio

Tim De Chant — 7:00 AM PDT · May 30, 2023

Few fields are changing as quickly as climate tech. In the last five years, it's undergone a radical transformation, blossoming from a niche area to a broad sector full of promising niches. With that diversification comes risk and opportunity.

Latest in Climate

See More

And choices. So, so many choices. With the world looking to revamp nearly every corner of the global economy, there is a seemingly unending supply of startups in which to invest. There's no way to create a definitive list, but here are three areas that deserve a closer look.

Enhanced rock weathering

With humans on track to blow through the "safe" amount of global warming in less than five years, carbon removal has been getting a lot of attention. There are lots of ways to do it, too: from big carbon filters and enhanced algae to rocks. Yes, rocks.

Several types of rocks naturally draw carbon dioxide from the atmosphere and transform it into a stable mineral. Problem is, that process is happening too slowly to have any effect on the colossal amounts of carbon we've pumped into the atmosphere.

One of the easiest ways to speed that process up is to expose more rock to the atmosphere by crushing it to bits and spreading it out over a wide area. That may not sound very appealing, but it is to farmers.

Farmers already spend lots of money on soil amendments, which includes everything from synthetic fertilizers to compost and manure. In certain regions with acidic soils, farmers also apply crushed limestone to raise the pH in the area.

More than a few startups, including [Lithos Carbon](#) and [Eion](#), have latched on to this idea. But instead of spreading lime, they substitute it for another pulverized rock, like basalt or olivine, that can suck carbon from the air.

Two things make enhanced rock weathering appealing to investors. One, the cost per ton of carbon removed is pretty low, ranging anywhere between [\\$80 and \\$180 per ton](#). That's far below the costs of direct air capture, which involves big fans blowing air over filters to strip it of the dilute amount of carbon dioxide that regular air contains. Enhanced rock weathering could remove up to two metric gigatons of carbon dioxide every year.

Second, we have the tech. None of this would work if the startups didn't have sophisticated models to accurately predict how much carbon an acre of farm field can remove. Crushing, hauling and spreading rock isn't hard — that stuff can all be subcontracted — but the modeling and verification is.

If, as many people suspect, carbon removal becomes a service akin to wastewater treatment or garbage collection, then the demand for such platforms will be enormous.

Fusion

Commercial fusion power practically defines high-risk/high-reward investment. What investor wouldn't want at least one bet like this in their portfolio?

Fusion's potential is often described as limitless, and that epithet isn't unwarranted. Supply is practically unlimited: Depending on the technology, the Earth could have thousands or millions of years of fuel on hand.

If fusion reactors can be built at scale for a reasonable cost, demand certainly won't be a problem. Last year, consumers paid over \$10 trillion for energy, the IEA [estimates](#). How many other markets have a potential TAM in the trillions?

Plus, the odds of fusion succeeding have [increased significantly in recent years](#). New magnets have enabled designs for fusion plants that are smaller and cheaper to run, tipping the balance toward profitability. And the [breakthrough experiment](#) at the Department of Energy's National Ignition Facility has boosted hopes that sustainable, profitable fusion power may finally be within reach.

There are a range of investment opportunities, too. We have [unicorn-scale startups and suppliers](#) as well as smaller outfits that are taking a [lean-and-mean approach](#) to reactor design and development.

Fusion may not pan out, but if it does, the winners could make Exxon look small by comparison.

Grid management software

What venture portfolio would be complete without a SaaS play? As the climate tech matures, there will be plenty of SaaS opportunities, but one area that's particularly promising today is software to help manage the increasingly vital and soon-to-be-overwhelmed electrical grid.

Electrifying the economy will require major grid upgrades, which won't come cheap. The Department of Energy is providing [\\$13 billion in financing](#) to help ease the burden, but that's nothing compared to the estimated [trillions](#) of dollars we'll need.

Grid management software could pare those costs, though. Instead of spending money on physical upgrades, software can help find efficiencies. LineVision, for example, monitors high-voltage transmission lines to determine the maximum amount of electricity they can carry at any given moment. In many cases, that's [higher than the line was originally rated for](#), usually 15% to 40% more.

Electric vehicle charging is another wildcard that utilities are planning upgrades around. Since EVs draw massive amounts of power, there's the potential to overwhelm transformers if too many people plug in at once. To minimize the chances of that, WeaveGrid [helps coordinate power supply](#), giving both automakers and utilities windows into drivers' charging behaviors.

The beauty of software-driven solutions is their inherent flexibility and broad applicability. As the grid is upgraded, there will arise new avenues for software to interface with it. SaaS-like niches will multiply, creating ample opportunities for investors.

Because the customers are utilities, the sales cycles are bound to be long, and runways will have

to be, too. But once a startup has proven itself, the contracts are usually lucrative and long term, improving returns.

Balancing risk and opportunity

Climate tech has only taken off in the last few years, and many investors are still finding their footing in this ever-changing landscape. Change means opportunity, though, and as the sector continues to evolve, so will investment strategies.

The three technologies listed above aren't the final word in climate tech investing, but they do offer a decent balance between risk and safety. All that's left is picking the winners.

An Investment Opportunity In Trash

S. H. Jucha — 1:00 PM PST · December 20, 2015

IMAGE CREDITS: [RONSTIK](#) / [SHUTTERSTOCK](#)

As incredible as it might seem, processing trash may represent a future unique investment opportunity. Consider the new technologies that will operate on the micro scale, breaking the bonds of molecules through bio-mechanical means, which could be applied to recycling trash completely. It is quite possible that many of these innovations may emerge from our efforts to explore and live in space.

Since the dawn of the Industrial Age, we have polluted our streams, rivers, lakes and oceans with pesticide and fertilizer runoff, mining and oil

Advertisement

TC DISRUPT

October 27-29, 2025 | San Francisco

wastes, petrochemical products and thousands of other dangerous products.

Pollution has reached the point where a cleanup of our environment — on a macro scale with heavy equipment — is impractical. Despite present efforts, humanity is losing the fight to manage trash.

Commercial and government-mandated recycling can't cope with the sheer volume of trash, and these programs only excel at processing such material as paper, aluminum and steel. In essence, the present forms of trash collection and recycling are unacceptable.

The opportunity for investment in effective trash processing will be huge. We have discarded billions of tons of plastic across our planet in the last 60 years. So much debris has accumulated in the Pacific Ocean that it has been termed the Great Pacific Garbage Patch. [Scientists](#) believe that the trash has been sinking beneath the surface, making accurate measurement of the amount of trash difficult.

[Plastics](#), whose durability, inexpensiveness and malleability make it an easy choice for consumer and industrial products, make up the majority of the garbage patch debris. In a process called [photo degradation](#), which is caused by the ultra violet (UV) component of solar radiation (that is, radiation of wavelength from 0.295 to 0.400 um), the plastics have been broken down into smaller and smaller pieces. [National Geographic](#) states that scientists have collected up to 750,000 bits of micro-plastic in a single square kilometer of the Great Pacific Garbage Patch — that's about 1.9 million bits per square mile.

Put your brand in front of 10,000+ tech and VC leaders across all three days of Disrupt 2025. Amplify your reach, spark real connections, and lead the innovation charge. Secure your exhibit space before your competitor does.

Importantly, space exploration will not be a future of just probes launched to investigate asteroids and distant bodies — which I applaud — but, more importantly, the creation of long-term habitats, both government and commercial missions, which Buzz Aldrin appropriately calls “permanence.”

With the daunting challenges facing countries today — dwindling precious resources, effects of climate change, outbreaks of deadly diseases, long-term conflicts and mass human migration — 100 percent recycling/reclamation projects can't be high on their lists of priorities.

However, long-term space exploration will have the priorities of food, water, oxygen, fuels, environment control, protection from solar radiation *and* a growing pile of expended materials ... trash.

Long-term habitation will demand extremely efficient resource management of water, air, organics and inorganics ... those items that typically, when worn out, enter our trash piles and consist of everything from door seals to expended lubricants. Our scientists will have to approach the challenge of recycling with an eye toward 100 percent solutions, and recycling inorganics will present the greatest challenge.

Simply put, trash will cost too much to ship back to Earth, and it would be invaluable if this waste could be fully recycled into environmentally useful components. With Earth's resources dwindling, the better we can recycle and reclaim what today we call "trash" and repurpose it in our commercial products, the more we can extend the lifespan of Earth's resources.

Petrochemical products — from synthetic rubber and solvents to fibers and plastics — may be degraded by various micro-organisms, which break the carbon bonds to produce byproducts such as methane, carbon dioxide and water.

Space habitats represent an ideal environment to experiment with closed systems employing bio-engineered micro-organisms to recycle petrochemical products, where, in case of accidental release of the organisms, it might be opportune to open the test area to vacuum.

Why experiment with bio-engineered micro-organisms? Why not? There are plenty of examples that give credence to the concept:

Forty years ago, [Shinichi Kinoshita, Sadao Kageyama, Kazuhiko Iba, Yasuhiro Yamada and Hirosuke Okada](#) discovered a strain of *Flavobacterium* that digested certain byproducts from the manufacture of nylon-6, a form of nylon fiber that is tough and possesses high-tensile strength, as well as elasticity. The fibers are wrinkle-proof and highly resistant to abrasion and chemicals such as acids and alkalis. The fact that bacterium began using as energy sources these substances that didn't exist before 1935 is a telling point. Microorganisms, with their prodigious reproduction rate, can quickly evolve to adapt to ever-changing environments.

A trip to the Amazon's Yasuni National Park by [Yale University students and molecular biochemistry professor Scott Strobel](#) resulted in the discovery of endophytic fungi (mushrooms) capable of eating polyurethane plastics. A synthetic polymer, polyurethane is the basis of most of today's plastics.

Methanogenic consortia, a diverse group of widely distributed archaebacteria that occur in anaerobic environments and are capable of producing methane from a limited number of substrates, including carbon dioxide, hydrogen, acetate and methylamines, have been found to degrade styrene, using it as a carbon source, and various fungi have broken down plasticized PVC.

An example of petrochemical degradation includes a rod-shaped bacterium, *Alcanivorax borkumensis*, found throughout the oceans. The [bacteria consume alkanes](#), a form of hydrocarbon, as their primary form of energy, breaking down hydrocarbons into carbon dioxide and water. These ancient bacteria, resident since the planet began seeping hydrocarbons from the ocean bottoms, bloomed in heavy quantities after the Deep Horizon oil spill in the Gulf of Mexico, and

contributed to the removal of hydrocarbons from the Gulf's waters.

The attack of microorganisms on petrochemicals has been continual since the advent of each product. Even [space station Mir](#) was found to have been growing more than 70 species of bacteria, mold and fungi in free condensate, floating water globules, hiding behind such areas as the station's electrical panels — and mold is capable of degrading rubber into digestible compounds.

Future space habitats, with their complete isolation, present an excellent opportunity for micro-scale waste management experiments that would involve genetically modified microorganisms. Unfortunately, these types of experiments will not be a priority in the early stages of habitats. Supplies will be too precious to be consumed in “nice-to-have” experiments.

However, when habitats graduate to the size of colonies, housing thousands of residents, “nice-to-have” may become “must-have,” and the pressure to develop efficient processes to recycle inorganics, such as plastics, will only increase as the colonies grow.

Creating and employing genetically engineered bacterium, fungi, yeasts, algae, lichens and the like to recycle petrochemical products — until such time as alternative, easily recyclable materials are developed — will be the responsibility of disciplines such as biochemists, geneticists and engineers — or collectively what I like to call waste management's bio-alchemists.

Whatever new technologies long-term space habitats invent to manage inorganic wastes, recycling the material into reusable components, construction products or other practical purposes, it's my fervent hope that they will translate into a

boon for solutions to Earth's problems. If they do, new techniques in recycling and pollution mitigation will represent a global business opportunity.

A first step on Earth might limit the applications to controlled facilities, processing trash from homes and businesses. Later, with subsequent iterations that limit the microorganisms' life cycles, the solutions may be applied to Earth's open waters and landscapes. Glory to the future of garbage management!

As an environmentalist, I do not see these future innovations as "nice to have." I see them as economic necessities. If we wish to have the luxury of time to investigate our solar system, building habitats on distant planets and moons and involving commercial ventures, we must ensure the health of the global economic base from which the funds and resources will spring to feed our space exploration endeavors.

At present, our [global population](#) is estimated to be 7.27 billion people; by the mid-21st century, this number is expected to reach [9.6 billion](#). Regardless of the extent of our ventures into space, the overwhelming majority of these people will remain on Earth, and they will require a healthy and safe environment if they are to contribute to the global economy. Ensuring humans live in an invigorating environment would not only be good economics, it would be the right thing to do.

Perhaps in the future, commercial products may be created through technologies such as nano-manufacturing. It would eliminate much of the problem of inventing recycling methods or finding places to bury our trash, because these products could be repaired or recycled by reversing the nano-manufacturing process.
